Kawabata T., Nishikawa K."Protein tertiary structure comparison using the Markov transition model of evolution" (2000). *Proteins*, **41**, 108-122.

1 What is MATRAS ?

MATRAS is the program sets for protein 3D structure comparison, it stands for *Markovian TRAnsition of protein Structure*. Its advantage is its score using Markov transition model of structure evolution, which is supposed to be better for detecting homologous structure similarity. At the beginning, MATRAS was developing in National Institute of Genetics (Mishima, Japan), by Takeshi Kawabata, who was a post-doctoral research fellow under the supervision of Prof. Ken Nishikawa. That was around 1998. The first purpose was basically for estimating accuracies for protein structure predictions (fold recognition) of CASP3. Its method was published in 2000, in *Proteins*. After that, the several functions, such as 3D library search and multiple 3D alignment, are added to the original MATRAS program. The WEB server of 3D structure comparison is also available (http://biunit.naist.jp/matras).

2 Method for comparing 3D structures

2.1 Definition of Similarity Scores

The structure similarity score of MATRAS is defined as a following log-odds score :

$$S(i,j) = \log \frac{P(i \to j)}{P(j)} \tag{1}$$

where $P(i \to j)$ is the transition probability that structure i changes to structure j during the evolutionary process, and $P(i)$ is the probability that structure i appears by chance. i and j can represent any kinds of 3D structural features, such as secondary structures and distance between residues. Generally speaking, estimation of the transition probability $P(j \to i)$. We estimated the transition probability by the Markov transition model, which is similar to Dayhoff's substitution model between amino acids. Matras uses the following three kinds of similarity scores.

(1) **SSE Score** S_{sse}

A secondary structure element (SSE) is a continuous residue group that is defined as an α-helix a β-strand. It is represented by a single vector defined by the principle inertial axis with the smallest moment. The spatial arrangement of a pair of SSEs is described by six parameters : the number of residues L_1, L_2, the closest distance between SSE pairs d, the bond angles θ_1,θ_2, and the dihedral angle ϕ. And we made six kinds of log-odds score corresponding six parameters, the total SSE score is represented as the sum of six terms.

(2) **Environment Score** S_{env}

This score was defined for the environment states, which are a combination of local structure and solvent accessibility. The ten kinds of "environment" are defined by combining the five local structures and the two accessibility classes.

(3) **Distance Score** S_{dis}

This score focuses on the distance between C^{β} atoms of the ith and jth residues. The distance is transformed into a discrete histogram with 1 $\mathring{A}$ width. This score is prepared for each residues separation k $(=|i-j|)$. It is used in the final stage of alignment of our program, because it is the most sensitive to detect structural similarity among our three scores.

2.2 Alignment Strategy

It it difficult to find the structural corresponding residues (alignment) with the largest two-body similarity score (such as the SSE score and the distance score). We use the most popular heuristics, "hierarchical alignment", in which a rough alignment is first obtained by the SSEs, then the alignment is improved with more detailed similarity functions. Our procedures of hierarchical alignment consists of the following three stages.

(1) **Make a SSE alignment using** S_{sse}

Build-up method is used for finding the corresponding SSEs.

(2) **Preliminary DP alignment using** S_{env}

A dynamic programming alignment with S_{env} is performed, using restriction of previously aligned SSEs.

(3) **Iterative DP Alignment using** S_{dis}

A dynamic programming alignment with the distance score S_{dis} is iteratively performed using the alignment determined in the previous stage.

3 Installations

3.1 Required Environment

- **OS:** UNIX

  The original Matras was developed on SGI-IRIX workstation, and now maintained in Linux machines. We believe that it may work on any other UNIX systems, although we confirm only two environment (IRIX and Linux).

- **Programming Language:** C and Perl

  The main program of Matras is written in C, and other additional programs are written in Perl, such as making BSSP file, superimposed structures and multiple 3D alignment. To install and use Matras, you must prepare a C compiler and a Perl interpreter.

- **DSSP**

  Matras needs a program DSSP (Kabsh and Sander,1983) to assign secondary structures of proteins, for making BSSP files. You must download the source code from the site (http://swift.cmbi.ru.nl/gv/dssp/index.html), and install the DSSP program (dsspcmbi).

- **RasMol**

  A molecular graphic program is necessary to see superimposed structures obtained by Matras. We recommend the program RasMol for our purpose. The RasMol is the most popular freeware, it can work on most of UNIX platform. If you don't have RasMol in your computer, go to http://www.OpenRasMol.org and install it.

3.2 Procedures for Install

(1) Download the compressed source file "Matras[version].tar.gz"

(2) ungzip the file and extract all the files.

```
% ungzip Matras[version].tar.gz
% tar xvf Matras[version].tar
```

New directory "Matras[version]" appears.

(3) Go to src directory

```
% cd Matras[version]/src
```

(4) Edit "Makefile" for adjusting your environment.

The default makefile assumes that a user uses the gcc compiler. We also prepare a makefile for SGI ("Makefile.sgi").

(5) Make it

```
% make
```

If you succeed, an executable file "Matras" is made at the upper directory of "src".

(6) Put the executable file "Matras" on your favorite binary directory, or add the Matras directory to your PATH variable.

3.3 Set your environment using ".matras" file

Matras reads environmental information from the file ".matras". You must put the ".matras" files on (1)your current directory, or (2)your home directory. A sample environmental file is shown as follows, which is stored as "dot.matras" in the base directory.

```
##############################
### MATRAS ENVIRONMENT FILE ###
##############################

BASE_DIR  /home/takawaba/work/Matras12
SCORE_DIR /home/takawaba/work/Matras12/data_sc/ROM-04JAN29
TMP_DIR   /home/takawaba/work/Matras12/tmpout
BSSP_DIR  /DB/BSSP
PDB_DIR   /DB/PDB
```

A line whose head is "#" is a comment that Matras skips to read. Other lines are combinations of [Variable Name] [Value of Variables]. We will explain important variables.

(1) **BASE_DIR** : a directory where Matras is installed.

(2) **SCORE_DIR** : a directory of Matras score files

(3) **BSSP_DIR** : a directory of BSSP files.

I will explain about BSSP files later.

(4) **TMP_DIR** : a directory for temporary files.

If you want to use multiple 3D alignments, you must assign TMP_DIR.

3.4 Make BSSP files for your structures

3.4.1 What is BSSP?

Matras can read only special structure file : a "BSSP" file. Unfortunately, Matras cannot read PDB file directly. A BSSP file is an extension of DSSP file, which includes XYZ coordinates of C_β atoms, not only C_α atoms. We choose the format of BSSP files because of following three reasons. (1) Secondary structure information is required to compare 3D structure. (2) XYZ coordinates of C_β atoms is necessary to align protein pairs precisely, especially for β-strand regions. (3) A file size of BSSP is 1/10 of PDB file size. It enables us to search 3D structure more quickly.

A format of BSSP file is shown in Appendix.

3.4.2 How to make BSSP files

In order to make a BSSP file, you need a program of DSSP(named "dsspcmbi") and a Perl script "bssp.pl" (located in BASE_DIR). You must perform following two commands:

(1) `% dsspcmbi -c [pdb_file] [dssp_file]`

(2) `% bssp.pl [dssp_file] [pdb_file] > [bssp_file]`

For example, when you want to make a bssp file for myoglobin(PDBcode:1mbd), type as follows:

```
% dsspcmbi -c pdb1mbd.ent 1mbd-.dssp
% bssp.pl 1mbd-.dssp pdb1mbd.ent > 1mbd-.bssp
```

I recommend to add ".bssp" to the end of the bssp file as a suffix. In principle, Matras assumes that one BSSP file only contains one chain of protein. For the PDB files with multi chains, you must make a new PDB file that contains only one chain you want to compare.

The BSSP files must be located in one of the following three locations.

(1) the current directory when you execute Matras.

(2) BSSP_DIR, which is defined in the ".matras" file. If you want to deal with a large amount of structures, we recommend to put in the BSSP_DIR.

(3) BSSP_DIR/subdirectory. When you put a BSSP file in BSSP_DIR, its subdirectory is named as the second and third characters of the file name. This is a similar directory system to Protein Data Bank(PDB). For example, a file "1mbd-.bssp" is located in "BSSP_DIR/mb/", "4azuA.bssp" is located in "BSSP_DIR/az/".

3.5 Display HELP messages

If you input a following command,

```
% Matras
```

Matras shows simple help messages. A more detailed help messages are shown using a following command:

```
% Matras H
```

4 Pairwise 3D Alignment

Comparing two structures is the basic procedures of Matras. Other structural comparisons, such as libaray search and multiple alingment, are developed based on the pairwise 3D alingment.

4.1 Basic Operation

Basically, you can compare two structures by a following command:

```
% Matras P -A [bsspfileA] -B [bsspfileB] <options>
```

For example, if you want to compare myoglobin(1mbd-.bssp) and hemoglobin α chain (4hhbA.bssp), input a following command:

```
% Matras P -A 1mbd-.bssp -B 4hhbA.bssp
```

Then you get a following output in standard output.

```

4.2 Measures of Structure Similarities

The head lines of the outputs contain various kinds of structure similarities.

```
[ALIGN_RANK]  1
[PROTEIN A]   1mbd-    Naa 153 Nsse  8 "MYOGLOBIN (DEOXY, $P*H 8.4)"
[PROTEIN B]   4hhbA    Naa 141 Nsse  7 "HEMOGLOBIN (DEOXY)"
[ALIGNMENT]   Ncomp_aa 141 Ncomp_sse 6
[SIMILARITY]  Seq 27.0 %  Sec 88.7 % Exp 82.3 % CRMS 1.56 A  DRMS 1.40 A
[SCORE]       ScSSE 676.0 ScEnv 4007.8 ScDis 149312.6 Rdis 70.7 (%) Rsse 44.8 (%)
[RELIABILITY] Superfamily 100.0 %  Fold 100.0 %
```

- [**ALINGMENT**]

  Ncomp_aa : Number of compared (aligned) amino acids

  Ncomp_sse : Number of compared (aligned) SSEs

- [**SIMILARIRY**]

  Seq : sequence identity (%), defined as number of identical amino acid pairs divided by Ncomp_aa.

  Sec : secondary structure identitiy(%), defined as number of identical secondary structure residue pairs divided by Ncomp_aa. 8 states secondary structure of DSSP are used.

  CRMS : Root mean square deviation ($\mathring{A}$) of C^{α} atom positions of aligned residues, after optimal superimposition.

  DRMS : Root mean square deviation ($\mathring{A}$) of distances between C^{β} atom positions of aligned residues.

- [**SCORE**]

  ScSSE: SSE score S_{sse}.

  ScDIS: Distance score S_{dis}.

  Rdis :@Normalized S_{dis} score (%) using the maximum and minimum value of the score. This is for understanding the similarity more intuitively than the raw value of S_{dis}. R_{dis} between protein A and B is defined as follow :

$$R_{dis}(A,B) = 100 \cdot \frac{S_{dis}(A,B) - S_{min}}{S_{max} - S_{min}} \tag{2}$$

where $S_{dis}(A, B)$ is a raw distance score between protein A and B, S_{max} and S_{min} is the maximum and minimum value of the score correspondingly. We set $S_{min} = 0$, S_{max} is defined as the averaged value among the self scores:

$$S_{max} = \frac{S_{dis}(A, A) + S_{dis}(B, B)}{2} \tag{3}$$

- **[RELIABILITY]**: This values shows a probability that a structure pair with a normalized score R_{dis} is classified as the same superfamily/fold relationship. This values are estimated by all-vs-all comparison of protein domains in SCOP 1.71 database.

4.3 Output files

After calculation, Matras writes three files,"1.pdb", "1.ras" and "1.mat" in the current directory.

v

- **1.pdb**

  A PDB file that contains two superimposed structures. The optimal superposition is calculated for only aligned regions, but the file contains non-aligned regions. It contains only C^{α} and C^{β} atoms. A structure assigned by "-A" has a chain identifier 'A', and one assigned by "-B" has a 'B'. If you don't want to write this file, add the option **-op -**.

- **1.ras**

  A Rasmol script for coloring aligned residues in the superimposed PDB file "1.pdb". If you input the following command:

  ```
  % rasmol 1.pdb
  RasMol> script "1.ras"
  ```

  then RasMol shows a colored structure pairs. If you don't want to write this file, add the option **-or -**.

- **1.mat**

  This file contains the values of a translation vector and a rotation matrix for superimposing two structures.

4.4 Options for Input/Output

- **-oa** [CASP style pairwise alignment file]

  Write a pairwise alignment in the CASP style format (defined in Appendix).

- **-ia** [CASP style pairwise alignment file]

  Input a pairwise alignment in the CASP style format. If this option is assigned, Matras does not calculate an alignment by himself, only calculate similarities using the input alignment and write the results.

- **-ow** [ClustalW style pairwise alignment file]

  Write a pairwise alignment in ClustalW format.

4.5 Sub-optimal Alignment

A following option is for calculating sub-optimal alignment. Its default value is 'F'alse.

- **-SO** [T or F]

  If the option ''-SO T", then Matras calculate sub-optimal alignments. The default is "F"alse. If Matras recognize more than one optimal alignment, they show all the alignments in stdout, and write correspoinding RasMol scripts are "1.ras","2.ras"..”n.ras", correspoinding matrix files are "1.mat","2.mat"..”n.mat".

4.6 Sequence Alignment

A following option is for calculating simply sequence alignment. For some special cases (for example, identical protein pairs with large conformational change), sequence alignment is better than 3D alignment. Its default value is 'F'alse.

- **-SQ** [T or F]

  If the option ''-SO T", then Matras calcualate an alignment considering only amino acid type, not any 3D structure features. BLOSUM 62 score and gap penalty for extension is -1, and that for open is -11.

4.7 Self 3D Alignment

Self 3D alignment is to detect structurally similar regions in one proteins. It is useful for finding repeating units of proteins.

To run the self 3D alignment, you only run the pairwise 3D alignment assigning the same bsspfile for "-A" and "-B" options,and add "-SA T" option.

```
% Matras P -A [bsspfile] -B [bsspfile] -SA T
```

For example, if you want to find repeated structures of triose phosphate isomerase (TIM), run a following command.

```
% Matras P -A 1timA.bssp -B 1timA.bssp -SA T
```

You can use any other options for pairwise 3D alignments.

5 3D Library Search (one-vs-library)

This is for finding similar structures of a query structure in many library structures. This search requires a large computational costs. For example, a search of a query structure with 200 amino acids against 3000 library structures, takes 20-30 minutes using a Intel Pentium III 800 MHz CPU. The calculation time depends on the size of query protein and the number proteins in the library.

```
% Matras L -Q [query_bsspfile] -L [library_listfile] > [result_file]
```

The file [library_listfile] contains names of BSSP files for the structure library. The format of library list file is shown in Appendix.

5.1 Score Normalization for ranking similar structures

To rank the similar score, Matras employs N_{comp}^2 -fitted Z-score for S_{dis}, as the default option. Z-score is defined as follows :

$$Z(q,l) = \frac{S(q,l) - E(q)}{\sigma(q)} \tag{4}$$

where q and l represent proteins, $S(q,l)$ is the similarity score of proteins q and l, and $E(q)$ and $\sigma(q)$ are the average value and the standard deviation of score of protein q over the database. Our distance score S_{dis} correlates with the square of N_{comp}, which is the number of compared residues. We therefore employed a quadratic normalization, in which $E(q)$ and $\sigma(q)$ in Equation (4) are determined by the least-square fitting of the similarity score. The regression line $S_q^{reg}(q,l) = A_q N_{comp}^2(q,l) + B_q$ is calculated for the score $S(q,l)$ of the query protein q against proteins l stored in the database, by the fitting parameters A_q and B_q. Then, the $E(q)$ in Equation (4) is replaced by $S_q^{reg}(q,l)$. $\sigma(q)$ is obtained by the averaged error of the regression line, $\sigma(q) = \sqrt{\sum_l^{N_{pro}} [S(q,l) - S_q^{reg}(q,l)]^2 / N_{pro}}$, where N_{pro} is the number of protein chains in the database. Because we assume that all the parameters A_q,B_q, and $\sigma(q)$ should be derived from the non-homologous proteins, we repeat the esimation two times. First, all the proteins in the library are used to estimate the parameters. Using these parameters, we calculate Z-score for each protein. To extract non-homologous protein, we chose proteins with Z-score ≤ 4.0, and reesimate the parameters and Z-score using the extracted non-homologous proteins.

5.2 Options

- **-R** [q or Q or S or R]

  This option is how to determine ranks for similar structures.

  - **-R q**: The default option. Matras employs N_{comp}^2 fitted Zscore of S_{dis} using protein with the plain Z-score ≤ 4.0, described in the previous subsection (Equation(4)).

- **-R Q**: Matras employs N^2_{comp} fitted Zscore of S_{dis} using proteins with the N^2_{comp} fitted Z-score ≤ 4.0.
- **-R S**: Matras ranks structure by the plain Z score of S_{sse}. using protein with the plain Z-score ≤ 4.0.
- **-R R**: Matras ranks structures by the score R_{dis}, which is a normalized S_{dis} score, defined in Equation (2). The score R_{dis} has a lower discrimination power than the Z-scores, however, its performance is not affected by the structural library. If your structural library is small or redundant, we recommend to use the R_{dis} (-R R) option.

- **-zt**

  A threshold Z-score value for showing the similar structure list, in the case of "-R q", "-R Q" and "-R S". The default value is 5.0.

- **-rt**

  A threshold Z-score value for showing the similar structure list, in the case of "-R R". The default value is 10.0.

5.3 Output File for 3D Library Search

An example of the result of "3D Library Search" is shown at the end of this section. Basically, the result is composed of following six parts:

- header

  This part shows basic properties of a query structure and a structure library, such as size and number of proteins.

- [BEST_SCORE_RANKING]

  This part shows library structures whose Zscore is more than threshold, with following properties.

  - rk : rank. In default, entries are sorted by Zscore.
  - entry : entry code. Normally, it is a combination of PDBcode and Chain Identifier.
  - start : Residue number string of the first aligned residue of a library structure.
  - end : Residue number string of the last aligned residue of a library structure.
  - Rdis : Normalized S_{dis} score(%), defined in Equation (2).
  - Zsc : Zscore. In default, it is N^2_{comp} fitted Z-score of S_{dis}, defined in Equation (4).
  - SqID : Sequence Identity (%)

- [BEST_SCORE_RANKING_WITH_DETAILED_INFORMATION]

  This part shows library structures whose Zscore is more than threshold, with following properties.

- rk : rank. In default, entries are sorted by Zscore.
- entry : entry code. Normally, it is a combination of PDBcode and Chain Identifier.
- Naa : Number of amino acids of a library structure.
- Ncmp : Number of compared residues,N_{comp}.
- SqID : Sequence Identity (%)
- rms : RMSD of aligned C^{α} atoms (Å)
- Ssse : Score of SSE (S_{dis}).
- Rsse : Normalized Ssse score (%), defined in Equation (2).
- Sdis : Score of SSE (S_{sse}).
- Rdis : Normalized S_{dis} score (%), defined in Equation (2).
- Zsc : Zscore. In default, it is N_{comp}^2 fitted Z-score of S_{dis}, defined in Equation (4).
- RelS : Reliability(%) that a pair with this Zsc belongs to the same SCOP superfamily.
- RelO : Reliability(%) that a pair with this Zsc belongs to the same SCOP fold.

- [BEST_RANKING_WITH_ONE_LINE_SECONDARY_STRUCTURE]

  This part shows all the alignments between a query structure and library structures in one line, using secondary structure symbols. staQ and endQ represents start and end residues for query, staL and endL represents those for library. If Matras finds partial similarity, this part clearly shows where is the aligned region.

- [CLUSTALW_STYLE_ALIGNMENT]

  This part shows all the pairwise alignments as a master-slave multiple alignment. Note that this is not a multiple alignment in the strict meaning, because all the library structures are aligned to the query structure, not aligned between library structures.

- [ALIGNMENTS]

  This part shows all the pairwise alignment one by one. Their formats are exactly similar to that of "Pairwise 3D Alignment".

5.4 An example of the result of "3D Library Search"

A following long text is an example of the result of 3D library search, obtained by a following command.

```
% Matras L -Q 4azuA.bssp -L 30scop1.71nm.list -R q -zt 5
```

The query structure is "4azuA", and the library list file is "30scop1.71nm.list",which is the 30 % representative list of structural domains registered in SCOP 1.71.

```

6 All-vs-all 3D comparison

All-vs-all 3D comparison is a calculation of similarities for all the structural pairs in a library file.

```
% Matras A -L [library_listfile]
```

The format of libaray_listfile is described in the appendix. If a following listfile is used as inputs,

```
1mbd-
1ecd-
4hhbA
4hhbB
```

a following result will be obtained:

```

7 Multiple 3D Alignment

Multiple 3D alignment is a comparison more than two 3D structures, and getting alignments for these multiple structures. This is done by a Perl script name "mulmat.pl", which is in the BASE_DIR directory. This script calls the Matras program several times to get pairwise alignments, and it makes a multiple alignment by assembling these pairwise alignments.

7.1 Algorithm

Getting the optimal multiple alignment for sequences is a very hard computational problem, and getting the one for 3D structure is harder. Therefore, we employed a popular heuristics, called "progressive alignment", and it it done by simply assembling pairwise alignments.

- **Step1** : Calculate pairwise alignments and similarities for all structural pairs.

  The script "mulmat.pl" executes the Matras program, and stores all the results of pairwise alignment in the TMP_DIR directory (assigned in the ".matras" file).

- **Step 2** : Make a dendrogram using these similarities.

  The scripts executes a program "TreeUN" for making a dendrogram using UPGMA method.

- **Step 3**: Starting from the leaf nodes, progressively align all nodes, in order of decreasing similarity.

7.2 Basic Operation

If you execute **mulmat.pl** without any arguments, following help messages are shown:

```
% mulmat.pl [str1] [str2]... [strN] (-options)
  for 'mul'tiple 3D alignment using 'Mat'ras
  written by Takeshi Kawabata. LastModDate :Dec 26, 2003
 <options>
 -F       : strucutre list file[]
 -TMP_DIR : temporary output dir[/home/takawaba/work/Matras12/tmpout]
 -RES_DIR : result   output dir[.]
 -ad      : alignment file directory[]
 -ow      : Outfile in ClustalW[-]
 -ov      : Outfile in Vertical style[]
 -ovp     : Outfile in Vertical style with Plain Residue Num[]
 -oh      : Outfile in Horizontal style[]

 -ocon    : Outfile for consensus sequence []
 -opdb    : Outfile for sup-imposed PDBs[]
```

```
-oph     : Outputfile for guided UPGMA tree[]
-ops     : Outputfile PSI-BLAST multiple alignment[]
-OS      : Output StrType 'B'ssp, 'P'db [B]
-rhead   : header of all the result outputfile[]
-thead   : header of all the temporary outputfile[]
-so      : Matras SubOptimal[F]
-QO      : seQuence Order ('T'ree)[T]
-dmat    : Output distance matrix file[]
-smat    : Output similarity matrix file[smat]
-rm      : Remove Temoporary File (T|F) [F]
-M       : do MATRAS (T|F) [T]
-T       : do Tree (T|F) [T]
```

Its basic procedure to run is as follows:

```
% mulmat.pl [bsspfile1] [bsspfile2] [bsspfile3] ....
```

We show an example for multiple alignments of 1mbd-.bssp, 1ecd-.bssp, 4hhbA.bssp and 4hhbB.bssp. You can omit their tail string ".bssp".

```
% mulmat.pl 1mbd- 1ecd- 4hhbA 4hhbB
```

If you want to compare many structures, we recommend that you make a file that contains protein names (one protein per one line), and assign the file using "-F" option. For example, firstly, you make a following file named "listfile",

```
1mbd-
1ecd-
4hhbA
4hhbB
```

and execute "mulmat.pl" using a following options.

```
% mulmat.pl -F listfile
```

7.3 Options

- **-ow** [outputfile]

  Assign an output file name in ClustalW formats.

- **-ov** [outputfile]

  Assign an output file name in vertical formats, or CASP-style multiple alignment (its format is shown in Appendix).

- **-ovp** [outputfile]

  Assign an output file name in vertical formats, or CASP-style multiple alignment with plain residue number (its format is shown in Appendix).

- **-opdb** [output pdbfile]

  This option is for output superimposed multiple structures. It is not easy to find the optimal super imposition for multiple structures. We employ a simple strategy : first find the "center" structure, and superimpose other structures to the center one.

  Simultaneously, two RasMol scripts named "mulgrp.ras" and "mulchn.ras" are written. The former is coloring aligned regions, the latter is coloring by proteins. For example, if you want to color by aligned regions, you execute following commands:

```
rasmol [output pdbfile]
RasMol>script "mulgrp.ras"
```

- **-smat** [filename]

  Assign an output file for various similarities. It contains four kinds of similarities : R_{dis}, RMS, DRMS and SqID. The following is an example.

```
[RDIS(%)]
1mbd-              0.0  65.1  70.7  72.0
1ecd-             65.1   0.0  57.1  59.1

```

APPENDIX

A File format

A.1 BSSP

The BSSP file is very similar to the DSSP file. Only difference between them BSSP lacks the fields named “TCO”, “KAPPA” and “ALPHA” in DSSP files and has additional fields name “X-XB”, “Y-CB” and “Z-CB”, which are coordinates of C^{β} atoms.

```

```

A.2 CASP-style pairwise alignment

This is the format of pairwise alignment, which are used in CASP.

```
NPRO 2
PRO1 [Protein 1]
PRO2 [Protein 2]
COMMENT [Comment Line]
ALIGNMENT
[ResNum1] [ResName1] [ResNum2] [ResName2]
:
END
```

The residue names [ResName] must be written in one character way. The residue numbers [ResNum] must be identical to those in PDB files (23-27columns). If the ”RNUMPLAIN” line appears, then plain residue number (named from 1 by integer) are used. The residue name for a inserted/deleted position must be assigned as '-', and the residue number for indel position must be “-1”. Matras also output parameters for superimposing in this file. A following is an example.

```
NPRO 2
PRO1 1timA.bssp
PRO2 1kv8A.bssp
```

A.4 Library list file

This file is for the 3D library search, contains names of BSSP files for the structure library. The format is as follows :

```
#[COMMENT]
bsspfile_head1 comment_for_bsspfile1
bsspfile_headr2 comment_for_bsspfile2
:
:
#MAXLENGTH [MAXIMUM_AA_LENGTH_IN_LIBRARY]
```

The first field splited by spaces is for a library BSSP file. The following fields are for comments of each library structures. You can put anything such a protein name and a taxonomy id in these fields. The bottom line started by "#MAXLENGTH" is the maximum length of proteins in the library. If you omit this line, Matras uses the default value (1500 amino acids).

We show an example of a list file using SCOP taxonomy ID as comments.

```
